

1. I used 12 variables
2. Just two, only double and int
3. I decided on which variable types to use depending on what the program needed to do.
For example, I need a variable to hold a number with two numbers before the decimal so I used a double instead of float.
4. Print will just output whatever is on within the strings and not start a new line after, println will however print the output and also start a new line.
5. Yes I used both println and print. I used println when displaying the menu and final total, and only used print when I asked the user for an input so that the input will be on the same line where it was asked and not under it.
6. It will start a new line, creating a space between outputs in the console.
